# 1 Slide 4: Simple & Multiple Regression - Estimation

## 1.1 Regression Model

Assumption 1.1. Assuming the population follows

$$y = \beta_0 + \beta_1 x + u$$

and assume that x causes y.

## 1.2 OLS

$$\min_{\vec{\beta}} \sum_{i} (y_i - \hat{y}_i)^2$$
With FOC:
$$\sum_{i} (y_i - \hat{y}_i) = 0$$

$$\sum_{i} x_{ij} (y_i - \hat{y}_i) = 0, \ \forall j$$

**Remark 1.1.** Both  $\hat{\beta}_0$  and  $\hat{\beta}_j$  are functions of random variables and therefore themselves random with sampling distribution. And the estimated coefficients are random up to random sample chosen.

Property 1.1. Properties of OLS estimators

- Unbiased  $\mathbb{E}[\hat{\beta}|X] = \beta$
- Consistent  $\hat{\beta} \to \beta$  as  $n \to \infty$
- Efficient/Good min variance.

Definition 1.1. The Simple Coefficient of Determination

$$R^2 = \frac{SSE}{SST}$$

and  $SS\underline{Total} = SSExplained + SS\underline{Residual}$ 

$$\sum_{i} (y_i - \overline{y})^2 = \sum_{i} (\hat{y}_i - \overline{y})^2 + \sum_{i} (y_i - \hat{y}_i)^2$$

**Proposition 1.1** (Logarithms). Interpretation with logarithmic transformation.

- $\ln y = \alpha + \beta \ln y + u$ : x increases by 1%, y increases by  $\beta$ %.
- $\ln y = \alpha + \beta x + u$ : x increases by 1 unit, y increases by  $100\beta\%$ .
- $y = \alpha + \beta \ln x + u$ : x increases by 1%, y increases by 0.01 $\beta$  unit.

**Assumption 1.2.** Simple regression model assumptions

- 1. Model is linear in parameter.
- 2. Random samples  $\{(x_i, y_i)\}_{i=1}^n$ .
- 3. Sample outcomes  $\{x_i\}_{i=1}^n$  are not the same.
- 4.  $\mathbb{E}(u|x) = 0$  conditional on random sample x.
- 5. Error is homoskedastic.  $Var(u|x) = \sigma^2$  for all x.

Benefits of MLR compared with SLR

- More accurate causal effect estimation.
- More flexible function forms.
- Could explicitly include more predictors so  $\mathbb{E}(u|X) = 0$  is easier to be satisfied.
- MLR4 is less restrictive than SLR4.

Property 1.2. MLR OLS residual satisfies

$$\sum_{i} \hat{u}_{i} = 0$$

$$\sum_{i} x_{ji} \hat{u}_{i} = 0, \ \forall i \in \{1, 2, \dots, k\}$$

**Property 1.3.** MLR OLS estimators  $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k$  pass through the average point.

$$\overline{y} = \hat{\beta}_0 + \hat{\beta}_1 \overline{x}_1 + \dots + \hat{\beta}_k \overline{x}_k$$

Proof.

## 1.3 Partialling Out

#### 1.3.1 Steps

- 1. Regress  $x_1$  on  $x_2, x_3, \ldots, x_K$  and calculate the residual  $\tilde{r}_1$ .
- 2. Regress y on  $\tilde{r}_1$  with simple regression and find the estimated coefficient  $\hat{\lambda}_1$ .
- 3. Then the multiple regression coefficient estimator  $\hat{\beta}_1$  is

$$\hat{\beta}_1 = \hat{\lambda}_1 = \frac{\sum_i y_i \widetilde{r}_{1i}}{\sum_i (\widetilde{r}_{1i})^2}$$

Proof.

#### 1.3.2 Interpretation

This OLS estimator only uses the <u>unique variance</u> of one independent variable. And the parts of variation correlated with other independent variables is partialled out.

**Assumption 1.3.** Multiple Regression Assumptions

- 1. (MLR1) The model is linear in parameters.
- 2. (MLR2) Random sample from population  $\{(x_{1i}, \dots x_{ki}, y_i)_{i=1}^n$ .
- 3. (MLR3) No perfect multicollinearity.
- 4. (MLR4) Zero expected error conditional on population slice given by X.

$$\mathbb{E}(u|X) = \mathbb{E}(u|x_1, x_2, \dots, x_k) = 0$$

5. (MLR5) Homoskedastic error conditional on population slice given by X.

$$Var(u|X) = \sigma^2$$

6. (MLR6, strict assumption) Normally distributed error

$$u \sim \mathcal{N}(0, \sigma^2)$$

## 1.4 Omitted Variable Bias

Suppose population follows the real model

$$y_i = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_k x_{ki} + u_i \tag{1}$$

Consider the *alternative model*, and  $\underline{x_k}$  is omitted, which is assumed to be relevant.

$$y_i = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + \dots + \beta_{k-1} x_{(k-1)i} + r_i$$
 (2)

and use the partialling-out result on the second regression we have

$$\tilde{\beta}_1 = \frac{\sum_i \tilde{r}_{1i} y_i}{(\tilde{r}_{1i})^2}$$

where  $\tilde{r}_{1i} = x_{1i} - \tilde{\alpha}_0 - \tilde{\alpha}_2 x_{2i} - \dots - \tilde{\alpha}_{k-1} x_{(k-1)i}$ 

$$\tilde{\beta}_1 = \hat{\beta}_1 + \hat{\beta}_k \frac{\sum (\tilde{r}_{1i} x_{ki})}{\sum (\tilde{r}_{1i})^2}$$
 (3)

and take the expectation

$$\mathbb{E}(\tilde{\beta}_1|X) = \beta_1 + \tilde{\delta}_1\beta_k$$
$$Bias(\tilde{\beta}_1) = \tilde{\delta}_1\beta_k$$

**Conclusion** the sign of bias depends on  $cov(x_1, x_k)$  and  $\beta_k$ .

# 2 Slide 5: Matrix Algebra for Regression Analysis

$$\mathbf{y} = \mathbf{A}\mathbf{x} \implies \frac{\partial \mathbf{y}}{\partial \mathbf{x}} = \mathbf{A}$$
 (1)

Let  $\alpha = \mathbf{y}' \mathbf{A} \mathbf{x}$ , notice that  $\alpha \in \mathbb{R}$ , then

$$\frac{\partial \alpha}{\partial \mathbf{x}} = \mathbf{y}' \mathbf{A} \tag{2}$$

$$\frac{\partial \alpha}{\partial \mathbf{v}} = \mathbf{x}' \mathbf{A}' \tag{3}$$

Consider special case  $\alpha = \mathbf{x}' \mathbf{A} \mathbf{x}$ , then

$$\frac{\partial \alpha}{\partial \mathbf{x}} = \mathbf{x}' \mathbf{A} + \mathbf{x}' \mathbf{A}' \tag{4}$$

and if **A** is symmetric,

$$\frac{\partial \alpha}{\partial \mathbf{x}} = 2\mathbf{x}'\mathbf{A} \tag{5}$$

# 3 Slide 6: Multiple Regression in Matrix Algebra

## 3.1 The Model

#### Predictor

$$\mathbf{X} \in \mathbb{M}_{n \times (k+1)}(\mathbb{R})$$

where n is the number of observations and k is the number of features.

$$\mathbf{X} = \begin{bmatrix} 1 & x_{11} & \dots & x_{1k} \\ 1 & x_{21} & \dots & x_{2k} \\ \vdots & & & & \\ 1 & x_{n1} & \dots & x_{nk} \end{bmatrix}_{n \times (k+1)}$$

Model

$$\mathbf{y} = \mathbf{X}\vec{\beta} + \mathbf{u}$$

First order condition for OLS

$$\mathbf{X}'\hat{u} = \mathbf{0} \in \mathbb{R}^{k+1}$$

$$\iff \mathbf{X}'(\mathbf{y} - \mathbf{X}\hat{\beta}) = \mathbf{0} \in \mathbb{R}^{k+1}$$

Estimator

$$\hat{\beta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}$$

Proof. From the first order condition for the OLS estimator

$$\mathbf{X}'(\mathbf{y} - \mathbf{X}\hat{\beta}) = \mathbf{0}$$

$$\implies \mathbf{X}'\mathbf{y} - \mathbf{X}'\mathbf{X}\hat{\beta} = \mathbf{0}$$

$$\implies \mathbf{X}'\mathbf{y} = \mathbf{X}'\mathbf{X}\hat{\beta}$$

$$\implies \hat{\beta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}$$

and note that (X'X) is guaranteed to be invertible by assumption no perfect multi-collinearity.

#### Sum Squared Residual

$$SSR(\hat{\beta}) = \hat{u}' \cdot \hat{u} = (\mathbf{y} - \mathbf{X}\hat{\beta})' \cdot (\mathbf{y} - \mathbf{X}\hat{\beta})$$

## 3.2 Variance Matrix

Consider

$$\vec{z}_t = [z_{1t}, z_{2t}, \dots z_{nt}]'$$
  
 $\vec{z}_s = [z_{1s}, z_{2s}, \dots z_{ns}]'$ 

Notice that the variance and covariance are defined as

$$Var(\vec{z}_t) = \mathbb{E}[(\vec{z}_t - \mathbb{E}[\vec{z}_t])^2]$$
$$Cov(\vec{z}_t, \vec{z}_s) = \mathbb{E}[(\vec{z}_t - \mathbb{E}[\vec{z}_t])(\vec{z}_s - \mathbb{E}[\vec{z}_s])]$$

The variance matrix of  $\mathbf{z} = [z_1, z_2, \dots, z_n]$  is given by

$$Var(\mathbf{z}) = \begin{bmatrix} Var(z_1) & Cov(z_1, z_2) & \dots & Cov(z_1, z_n) \\ Cov(z_2, z_1) & \dots & & & \\ \vdots & & & & & \\ Cov(z_n, z_1) & \dots & & Var(z_n) \end{bmatrix}$$

$$= \begin{bmatrix} \mathbb{E}[(z_1 - \overline{z}_1)^2] & \mathbb{E}[(z_1 - \overline{z}_1)(z_2 - \overline{z}_2)] & \dots \\ \mathbb{E}[(z_2 - \overline{z}_2)(z_1 - \overline{z}_1)] & \dots & & \\ \vdots & & & & \\ \mathbb{E}[(z_n - \overline{z}_n)(z_1 - \overline{z}_1)] & \dots & \mathbb{E}[(z_n - \overline{z}_n)^2] \end{bmatrix}$$

$$= \mathbb{E}[(\mathbf{z} - \mathbb{E}[\mathbf{z}])_{n \times 1} \cdot (\mathbf{z} - \mathbb{E}[\mathbf{z}])'_{1 \times n}] \in \mathbb{M}_{n \times n}$$

In the special case  $\mathbb{E}[\vec{z}] = \vec{0}$ , variance is reduced to

$$Var(\mathbf{z}) = \mathbb{E}[\mathbf{z} \cdot \mathbf{z}']$$

**Residual** Since residual  $u_i$  are *i.i.d* with variance  $\sigma^2$ , the variance matrix of **u** is

$$Var(\mathbf{u}) = \mathbb{E}[\mathbf{u} \cdot \mathbf{u}'] = \sigma^2 \mathbf{I}_n$$

**Estimator** If  $\hat{\beta}$  is unbiased,  $\mathbb{E}[\hat{\beta}|\mathbf{X}] = \vec{\beta}$ , then

$$Var(\hat{\beta}|\mathbf{X}) = \mathbb{E}[(\hat{\beta} - \vec{\beta}) \cdot (\hat{\beta} - \vec{\beta})'|\mathbf{X}] \in \mathbb{M}_{(k+1)\times(k+1)}$$

# 4 Slide 7: Multiple Regression - Properties

## 4.1 Assumptions (MLRs) in Matrix Form

E.1. linear in parameter

$$y = X\vec{\beta} + u$$

**E.2.** no perfect multi-collinearity

$$rank(\mathbf{X}) = k + 1$$

**E.3.** Error has expected value of  ${\bf 0}$  conditional on  ${\bf X}$ .

$$\mathbb{E}[\mathbf{u}|\mathbf{X}] = \mathbf{0}$$

**E.4.** Error **u** is homoscedastic.

$$Var(\mathbf{u}|\mathbf{X}) = \sigma^2 \mathbf{I}_n$$

 ${f E.5.}$  Normally distributed error  ${f u}.$  Note that this assumption is relatively strong.

$$\mathbf{u} \sim \mathcal{N}(\mathbf{0}, \sigma^2 \mathbf{I}_n)$$

## 4.2 Properties of OLS Estimator

**Theorem 4.1.** Given *E.1. E.2. E.3.*, the OLS estimator  $\hat{\beta}$  is an unbiased estimator for  $\vec{\beta}$ .

$$\mathbb{E}[\hat{\beta}|\mathbf{X}] = \vec{\beta}$$

Proof.

$$\hat{\beta} = (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}$$
$$= (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'(\mathbf{X}\vec{\beta} + \mathbf{u})$$
$$= \vec{\beta} + (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{u}$$

Taking expectation conditional on X on both sides,

$$\mathbb{E}[\hat{\beta}|\mathbf{X}] = \vec{\beta} + (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{0} = \vec{\beta}$$

**Lemma 4.1.** Suppose  $\mathbf{A} \in \mathbb{M}_{m \times n}$  and  $\mathbf{z} \in \mathbb{M}_{n \times 1}$  then

$$Var(\mathbf{Az}) = \mathbf{A}Var(\mathbf{z})\mathbf{A}'$$

**Theorem 4.2.** Given  $E.1 \sim E.4$ 

$$Var(\hat{\beta}|\mathbf{X}) = (\mathbf{X}'\mathbf{X})^{-1}\sigma^2$$

Proof.

$$Var(\hat{\boldsymbol{\beta}}|\mathbf{X}) = Var((\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{y}|\mathbf{X})$$

$$= Var((\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'(\mathbf{X}\vec{\boldsymbol{\beta}} + \mathbf{u})|\mathbf{X})$$

$$= Var(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{u}|\mathbf{X})$$
By the lemma above,
$$= (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'Var(\mathbf{u}|\mathbf{X})[(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}']'$$

$$= (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'Var(\mathbf{u}|\mathbf{X})\mathbf{X}''(\mathbf{X}'\mathbf{X})^{-1}$$

$$= (\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\sigma^{2}\mathbf{I}_{n}\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}$$

$$= \sigma^{2}(\mathbf{X}'\mathbf{X})^{-1}$$

**Theorem 4.3** (Gause-Markov). Given  $E.1. \sim E.4.$ , the OLS estimator is the best linear unbiased estimator (BLUE).

(The best here means the OLS has the least variance among all estimators.)

#### 4.3 Variance Inflation

Let  $j \in \{1, 2, ..., k\}$ , then the variance of an individual estimator on particular feature j is

$$Var(\hat{\beta}_j) = \frac{\sigma^2}{(1 - R_j^2)SST_j}$$

where

$$SST_j = \sum_{i=1}^n (x_{ij} - \overline{x}_j)^2$$

and  $R_j^2$  is the coefficient of determination while regressing  $x_j$  on all other features  $x_i, \forall i \neq j$ .

**Definition 4.1.** The variance inflation on estimator for feature j is

$$VIF_j = \frac{1}{1 - R_j^2}$$

**Remark 4.1** (Interpretation). the standard error of estimator on a particular variable  $(\hat{\beta}_i)$  is *inflated* by it's $(x_i)$  relationship with other explanatory variables.

#### Solutions to high VIF

- 1. Drop the explanatory variable.
- 2. Use ratio  $\frac{x_i}{x_j}$  instead.
- 3. Ridge regression.

**Remark 4.2.** VIF highlights the importantce of **not** including redundant predictors.

# 5 Slide 8: Multiple Regression - Inference

Hypothesis Testing on multiple regression model

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_k x_{ik} + u_i$$

## 5.1 t-test for significance of individual predicator

Test statistic Given  $MLR.1 \sim MLR.6$  (need  $\mathbf{u} \sim \mathcal{N}(\mathbf{0}, \sigma^2 \mathbf{I}_n)$ ),

$$t = \frac{\hat{\beta}_j - b}{s.e.(\hat{\beta}_j)} \sim t_{n-k-1}$$

where

$$H_0: \beta_j = b$$
$$H_1: \beta_j(\neq, >, <)b$$

## 5.2 t-test for comparing 2 coefficients

Test statistic

$$t = \frac{(\hat{\beta}_i - \hat{\beta}_j) - b}{s.e.(\hat{\beta}_i - \hat{\beta}_j)} \sim t_{n-k-1}$$

where

$$H_0: \beta_i - \beta_j = b$$
  
$$H_1: \beta_i - \beta_j (\neq, >, <) b$$

notice

$$s.e.(\hat{\beta}_i - \hat{\beta}_j) = \sqrt{Var(\hat{\beta}_i - \hat{\beta}_j)}$$
$$= \sqrt{Var(\hat{\beta}_i) + Var(\hat{\beta}_j) - 2Cov(\hat{\beta}_i, \hat{\beta}_j)}$$

## 5.3 Partial F-test for joint significance

$$H_0: \beta_i = \beta_j = \beta_k = \dots = 0$$
  
$$H_1: \exists \ z \in \{i, j, k, \dots\} \ s.t. \ \beta_z \neq 0$$

Test significance by comparing the *restricted* and *unrestricted* models, see whether restricting the model by removing certain explanatory variables "significantly" hurts the fit of the model.

$$df = (q, n - k - 1)$$

Test statistic

$$F = \frac{(SSR_r - SSR_{ur})/q}{SSR_{ur}/(n-k-1)} \sim F_{(q,n-k-1)}$$
 or 
$$F' = \frac{(R_{ur}^2 - R_r^2)/q}{(1 - R_{ur}^2)/(n-k-1)} \sim F_{(q,n-k-1)}$$

## 5.4 Full F-test for the significance of the model

$$H_0: \beta_1 = \beta_2 = \dots = \beta_k = 0$$
  
 $H_1: \exists i \in \{1, 2, \dots, 3\} \ s.t. \ \beta_i \neq 0$ 

**Remark 5.1.**  $R^2$  version only and substitute  $R_r^2 = 0$ , since  $SSR_r$  is undefined.

Test statistic

$$F = \frac{R_{ur}^2/k}{(1 - R_{ur}^2)/(n - k - 1)} \sim F_{(k, n - k - 1)}$$

## 5.5 F-test for general restrictions

**Remark 5.2.** Use the SSR version of Fstatistic only since the SST for restricted and unrestricted models are different.

**Remark 5.3.** We only reject or failed to reject  $H_0$ , we never accept  $H_0$  in a hypothesis test.

# 6 Slide 9: Multiple Regression - Further Issues

## 6.1 Data Scaling

#### 6.1.1 Mutiplier

- 1. Enlarge  $x_j$  by factor a:  $\hat{\beta}_j$  shrinks by a.
- 2. Enlarge y by factor a: all  $\hat{\beta}_i$  enlarged by a.
- 3. Test statistic  $t = \frac{\hat{\beta}}{s.e.(\hat{\beta})} = \frac{a\hat{\beta}}{s.e.(a\hat{\beta})}$  is unaffected.

## 6.1.2 Standardization

Standardized variable For  $j^{th}$  observation of explanatory variable x,

$$z_j = \frac{x_j - \overline{x}}{\sigma_x}$$

which satisfies

$$\mathbb{E}[z_j] = 0, \ Var(z_j) = 1$$

**Properties** Consider model and find the estimator of regressing standardized y on standardized x.

$$y_i = \hat{\beta}_0 + \hat{\beta}_1 x_{i1} + \dots + \hat{\beta}_k x_{ik} + \hat{u}_i$$

Since OLS estimator passes through the mean,

$$\overline{y} = \hat{\beta}_0 + \hat{\beta}_1 \overline{x}_1 + \dots \hat{\beta}_k \overline{x}_k$$

$$\implies (y_i - \overline{y}) = \hat{\beta}_1 (x_{i1} - \overline{x}_1) + \dots + \hat{\beta}_k (x_{ik} - \overline{x}_k) + \hat{u}_i$$

$$\implies \frac{y_i - \overline{y}}{\sigma_y} = \frac{\hat{\beta}_1 \sigma_{x_1}}{\sigma_y} \frac{x_{i1} - \overline{x}_1}{\sigma_{x_1}} + \dots + \frac{\hat{\beta}_k \sigma_{x_k}}{\sigma_y} \frac{x_{ik} - \overline{x}_k}{\sigma_{x_k}} + \frac{\hat{u}_i}{\sigma_y}$$

$$\implies b_j = \frac{\hat{\beta}_j \sigma_{x_j}}{\sigma_y}$$

**Remark 6.1** (Interpretation).  $x_j$  increases by 1 std, y increases by  $b_j = \frac{\hat{\beta}_j \sigma_{x_j}}{\sigma_y}$  std, ceteris paribus.

## 6.2 Logarithmic Function

**Exact** interpretation of log transformation.

$$\ln(y_i) = \hat{\beta}_0 + \hat{\beta}_1 x_{i1} + \dots \hat{\beta}_k x_{ik} + \hat{u}_i$$

Derive.

$$\ln(y_2) - \ln(y_1) = \hat{\beta}_j \Delta x_j$$

$$\implies \ln(\frac{y_2}{y_1}) = \hat{\beta}_j \Delta x_j$$

$$\implies \frac{y_2}{y_1} = \exp(\hat{\beta}_j \Delta x_j)$$

$$\implies \frac{y_2 - y_1}{y_1} = \frac{y_2}{y_1} - 1$$

$$\implies \% \Delta y = \exp(\hat{\beta}_i \Delta x_j) - 1$$

## 6.3 Quadratics and Polynomials

Model

$$y_i = \sum_{p=0}^k \beta_p x_i^p + u_i$$

Remark 6.2. Consider the interpretation and turning points.

#### 6.4 Interaction Effects

Consider model

$$y = \beta_0 + \beta_1 x + \beta_2 z + \beta_3 x z + u$$

then

$$\frac{\partial y}{\partial x} = \beta_1 + \beta_3 z$$

- 1. The effects of change of x on y depends on z.
- 2. Interpretation:  $evaluate \frac{\partial y}{\partial x}$  at a z point that we are interested in.
- 3. Use conventional testing (t-test) to check if interaction term is significant.

## 6.5 Regression Selection and Adjusted R-square

The adjusted R-square,  $\overline{R^2}$ , incorporates a *penalty* for including more regressors (if insignificant).

$$\overline{R^2} = 1 - \frac{(1 - R^2)(n - 1)}{n - k - 1}$$

**Remark 6.3.**  $\overline{R^2}$  increases when adding new regressor(or a group of regressors) if and only if the t value (F) for the individual regression(group of regressors) is more than 1.

#### 6.6 Causal Mechanism

### 6.7 Confidence Interval for Prediction

Consider a prediction

$$\hat{y} = \hat{\beta}_0 + \hat{\beta}_1 x_1 + \hat{\beta}_2 x_2 + \dots \hat{\beta}_k x_k$$

Evaluate at an arbitrary data point (not necessarily an observation in sample)

$$\mathbf{c} = (c_1, c_2, \dots, c_k)$$

Then the estimation of y at c is

$$\theta_0 = \mathbb{E}[y|x_1 = c_1, x_2 = c_2, \dots x_k = c_k]$$

$$= \beta_0 + \beta_1 c_1 + \beta_2 c_2 + \dots + \beta_k c_k$$

$$\implies \beta_0 = \theta_0 - \beta_1 c_1 - \beta_2 c_2 - \dots - \beta_k c_k$$

substitute back into the model

$$y = \theta_0 + \beta_1(x_1 - c_1) + \beta_2(x_2 - c_2) + \dots + \beta_k x_k + u$$

And the <u>margin of error</u> of confidence interval of prediction of y at  $\mathbf{c}$  can be found by inspecting the intercept on above regression.

$$ME = t_{\frac{\alpha}{2}} \times s.e.(intercept)$$

The center of confidence interval can be found from

$$\hat{\theta}_0 = \hat{\beta}_0 + \hat{\beta}_1 c_1 + \dots + \hat{\beta}_k x_k$$

The  $\alpha$  confidence interval is given by

$$\hat{\theta}_0 \pm ME$$

# 7 Slide 10: Multiple Regression - Qualitative Information

## 7.1 Binary predictors

**Remark 7.1.** With binary independent variables,  $MLR.1 \sim MLR.6$  still holds, but the interpretations are different.

#### 7.1.1 On Intercept

$$y = \delta_0 + \delta_1 male + \cdots + u$$

Remark 7.2. To avoid perfect multi-collinearity, never include all categories.

#### 7.1.2 On Slopes

$$y = \delta_0 + (\delta_1 + \delta_2 male) \times education + \dots + u$$

#### 7.1.3 F-test(Chow test)

Test whether the <u>true coefficients</u> in 2 linear regression models (e.g. for different gender groups) are equal.

1. Restricted model  $(SSR_r)$ 

$$y = \beta_0 + \beta_1 x + u$$

2. Unrestricted model  $(SSR_{ur})$ 

$$y = (\beta_0 + \delta_0 indicator) + (\beta_1 + \delta_1 indicator)x + u$$

3. Test whether the additional factors in coefficients  $(\delta_0, \delta_1)$  are significant. (q=2 in this case)

$$F = \frac{(SSR_r - SSR_{ur})/q}{SSR_{ur}/(n-k-1)}$$

#### 7.2 Linear Probability Model

Qualitative binary dependent variable

$$y = \beta_0 + \beta_1 x_1 + \dots + \beta_k x_k + u, \ y \in \{0, 1\}$$

**Interpretation** the model above predicts the probability of y = 1.

Proof.

$$\mathbb{E}[y|\mathbf{x}] = 0 \times Pr(y = 0|\mathbf{x}) + 1 \times Pr(y = 1|\mathbf{x})$$
$$= Pr(y = 1|\mathbf{x})$$

Remark 7.3.  $\beta_j = \frac{\partial P(\mathbf{x})}{\partial x_j}$  is the response probability, and  $\hat{P}(\mathbf{x})$  is the predicted probability of y to be 1.

**Remark 7.4** (Out-of-range predictions). Notice the prediction is not necessarily with the range of [0, 1] for some extreme values of  $\mathbf{x}$ .

## 7.3 Heterskedasticity of LPM

**Remark 7.5.** For probability linear models, MLR.5 (homoskedasticity) fails. *Proof.* 

$$y_{i} = \beta_{0} + \beta_{1}x_{i1} + \dots \beta_{k}x_{ik} + u_{i}$$
For binary  $y$ 

$$Var(u) = Var(y) = Pr(y = 1)(1 - Pr(y = 1))$$

$$Var(u|\mathbf{x}) = Var(y - \beta_{0} - \beta_{1}x_{1} - \beta_{2}x_{2} - \dots - \beta_{k}x_{k}|\mathbf{x})$$

$$= Var(y|\mathbf{x})$$

$$= Pr(y = 1|\mathbf{x})(1 - Pr(y = 1|\mathbf{x}))$$

$$= \mathbb{E}[y|\mathbf{x}](1 - \mathbb{E}[y|\mathbf{x}])$$

$$= (\beta_{0} + \beta_{1}x_{1} + \dots + \beta_{k}x_{k})(1 - \beta_{0} - \beta_{1}x_{1} - \dots - \beta_{k}x_{k})$$

$$\neq \sigma_{y}^{2}$$

# 8 Slide 11: Heteroskedasticity

**Definition 8.1.** Consider model

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_k x_{ik} + u_i$$

the error of above model is heteroskedastic if for each sample point  $\mathbf{x}_i \in \mathbb{R}^{k+1}$ ,

$$Var(u_i|\mathbf{x}_i) = \sigma_i^2$$

and  $\sigma_i^2$  is not the same for all i.

**Remark 8.1** (Consequence). Without MLR.5, Gauss-Markov theorem does not hold and

- 1. OLS estimator is still linear and unbiased.
- 2. But **not** necessarily the best (variance is affected).

Proof. unbiasedness, in simple regression.

$$\hat{\beta}_1 = \frac{\sum_i (x_i - \overline{x})(y_i - \overline{y})}{\sum_i (x_i - \overline{x})^2}$$

$$= \frac{\sum_i (x_i - \overline{x})(\beta_0 + \beta_1 x_1 + u_i - \overline{y})}{\sum_i (x_i - \overline{x})^2}$$

$$= \frac{\sum_i (x_i - \overline{x})(\beta_0 + \beta_1 x_1 + \beta_1 \overline{x} - \beta_1 \overline{x} + u_i - \overline{y})}{\sum_i (x_i - \overline{x})^2}$$

$$= \frac{\sum_i \beta_1 (x_i - \overline{x})^2 + (x_i - \overline{x})(\beta_0 + \beta_1 \overline{x} - \overline{y} + u_i)}{\sum_i (x_i - \overline{x})^2}$$

$$= \beta_1 + \frac{\sum_i (x_i - \overline{x})(0 + u_i)}{\sum_i (x_i - \overline{x})^2}$$

$$= \beta_1 + \frac{\sum_i (x_i - \overline{x})u_i}{\sum_i (x_i - \overline{x})u_i}$$

$$= \beta_1 + \frac{\sum_i (x_i - \overline{x})u_i}{\sum_i (x_i - \overline{x})^2}$$

taking expectation conditional on  $\mathbf{x}$  on both sides

$$\mathbb{E}[\hat{\beta}_1|\mathbf{x}] = \beta_1$$

Proof. variance.

$$Var(\hat{\beta}_{1}|\mathbf{x}) = \mathbb{E}[(\hat{\beta} - \mathbb{E}[\hat{\beta}_{1}|\mathbf{x}])^{2}|\mathbf{x}]$$

$$= \mathbb{E}[(\hat{\beta}_{1} - \beta_{1})^{2}|\mathbf{x}]$$

$$= \mathbb{E}[(\frac{\sum_{i}(x_{i} - \overline{x})u_{i}}{\sum_{i}(x_{i} - \overline{x})^{2}})^{2}|\mathbf{x}]$$

$$= \frac{\sum_{i}(x_{i} - \overline{x})\mathbb{E}[u_{i}|\mathbf{x}]}{\left(\sum_{i}(x_{i} - \overline{x})^{2}\right)^{2}}$$

$$\neq \frac{\sigma^{2}}{SST_{x}}$$

For multiple regressions

$$Var(\hat{\beta}_j|\mathbf{x}) = \frac{\sum_i \tilde{r}_{ij}^2 \sigma_i^2}{SSR_j^2} \neq \frac{\sigma^2}{SSR_j} = \frac{\sigma}{(1 - R_j^2)SST_j}$$

#### Remedies

1. Change variables so that the new model is homoskedastic.

- 2. Use robust standard errors.
- 3. Generalized least square (GLS).

### 8.1 Robust Standard Errors

**Idea** use  $\hat{u}_i^2$  to estimate  $\sigma_i^2$ .

Note that

$$Var(u_i|\mathbf{x}) = \mathbb{E}[(u_i - \mathbb{E}[u_i])^2]$$
$$= \mathbb{E}[u_i^2|\mathbf{x}] + \mathbb{E}[u_i|\mathbf{x}]^2$$
$$= \mathbb{E}[u_i^2|\mathbf{x}]$$

Consider model

$$y_i = \beta_0 + \beta_1 x_i + u_i$$

OLS estimator is

$$\hat{\beta}_1 = \beta_1 + \frac{\sum_i (x_i - \overline{x}) u_i}{\sum_i (x_i - \overline{x})^2}$$

$$Var(\hat{\beta}|\mathbf{x}) = \frac{\sum_i (x_i - \overline{x})^2 \sigma_i^2}{\sum_i (x_i - \overline{x})^2}$$

$$\widehat{Var}(\hat{\beta}|\mathbf{x}) = \frac{\sum_i (x_i - \overline{x})^2 \hat{\mathbf{u}}_i^2}{\sum_i (x_i - \overline{x})^2}$$

## 8.2 Test for Heteroskedasticity

### 8.2.1 General Principle

$$H_0: \mathbb{E}[u_i^2] = Var(u_i|\mathbf{x}) = \sigma^2$$
 (Homoskedastic)  
 $H_1: \mathbb{E}[u_i^2] = Var(u_i|\mathbf{x}) = \sigma_i^2$  (Heteroskedastic)

**Methodology:** specify the variance in alternative hypothesis to be a specific function of  $\mathbf{x}$  or y.

Consider the model:

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \dots + \beta_k x_{ik} + u_i$$

And  $H_1$  can be expressed as

$$H_1: \mathbb{E}[u_i^2|\mathbf{x}] = \delta_0 + \delta_1 z_1 + \delta_2 z_2 + \dots + \delta_p z_p$$

then run the proxy hypothesis testing

$$H'_0: \delta_1 = \delta_2 = \dots = \delta_p = 0, \delta_0 = \sigma^2$$
  
 $H'_1: \exists j \ s.t. \ \delta_i \neq 0$ 

Note that the restricted model is homoskedastic.

Firstly run the original regression model and get residual  $\hat{u}_i$ .

Then test the proxy hypotheses with regression  $\hat{u}_i^2$  on  $z_1, z_2, \dots, z_p$  using full F-test.

$$F = \frac{R_{\hat{u}^2}^2/p}{(1 - R_{\hat{u}^2}^2)/(n - p - 1)} \sim F_{(p, n - p - 1)}$$
 and  $nR_{\hat{u}^2}^2 \sim \mathcal{X}_p^2$ 

#### 8.2.2 Breusch-Pagan test

Use regressors  $x_i$  for  $z_i$ . Auxiliary regression:

$$\hat{u}_i^2 = \delta_0 + \delta_1 x_1 + \dots \delta_k x_k$$
$$nR_{\hat{n}^2}^2 \sim \mathcal{X}_k^2$$

#### 8.2.3 White test version 1

Use polynomials of  $x_i$  for  $z_i$ .

Auxiliary regression: (for the case of 2 regressors)

$$\hat{u}_{i}^{2} = \delta_{0} + \delta_{i1}x_{1} + \delta_{2}x_{i2} + \delta_{3}x_{i1}^{2} + \delta_{4}x_{i2}^{2} + \delta_{5}x_{i1}x_{i2} + \epsilon$$

$$nR_{\hat{u}^{2}}^{2} \sim \mathcal{X}_{5}^{2}$$
or full F-test

#### 8.2.4 White test version 2

Use <u>predicted</u> response  $\hat{y}$  (since its a linear combination of predictors) and its polynomial as  $z_i$ .

Auxiliary regression:

$$\hat{u}_i^2 = \delta_0 + \delta_1 \hat{y} + \delta_2 \hat{y}^2 + \epsilon$$

With hypotheses

$$H_0: \delta_1 = \delta_2 = 0$$
  
$$H_1: \delta_1 \neq 0 \lor \delta_2 \neq 0$$

$$nR_{\hat{u}^2}^2 \sim \mathcal{X}_2^2$$
 or full F-test

## 8.3 Generalized/Weighted Least Squared

## 9 Slide 12: Specification and Data Problems

A multiple regression model suffers from functional misspecification when it does not properly account for the relationship between the dependent and the observed explanatory variables.

## 9.1 Regression Specification Error Test (RESET)

#### 9.1.1 RESET: Nested Alternatives

Adding nonlinear functions of the regressors into the model and test for their significance.

Consider model

$$y = \beta_0 + \beta_1 x_1 + \dots + \beta_k x_k + u \tag{1}$$

If the original model satisfies MLR.4 ( $\mathbb{E}[u|\mathbf{X}] = 0$ ), then **no** nonlinear functions of the independent variables should be significant when added to equation (1).

#### **Procedures**

1. Add polynomials in the OLS fitted values,  $\hat{y}$ , to equation (1). Typically squared and cubed terms are added.

$$y = \beta_0 + \beta_1 x_1 + \dots + \beta_k x_k + \delta_1 \hat{y}^2 + \delta_2 \hat{y}^3 + u$$
 (2)

2. Use F-test to test the joint significance with  $H_0: \delta_1 = \delta_2 = 0$ . And a significant F suggests some sort of functional form problem.

$$F \sim \mathcal{F}_{(2,n-k-2)}$$

**Remark 9.1.** We will not be interested in the estimated parameters from (2); we only use this equation to test whether (1) has missed important nonlinearities.

Remark 9.2 (Nested Alternatives). One model is **nested** in another if you can always obtain the first model by constraining some of the parameters of the second model.

**Example 9.1.** In above example, the original regression is *nested* in the expanded regression. We can recover the original regression by constraining  $\delta_1 = \delta_2 = 0$  in the expanded model.

## 9.1.2 Non-nested Alternatives: RESET

Neither of the two models below is nested in the other one, we cannot use F-test.

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + u \tag{3}$$

$$y = \beta_0 + \beta_1 \log(x_1) + \beta_2 \log(x_2) + u \tag{4}$$

#### **Procedures**

1. Construct a *comprehensive model* that contains each model as a special case and then to test the restrictions that led to each of the models.

$$y = \beta_0 + \gamma_1 x_1 + \gamma_2 x_2 + \gamma_3 \log(x_1) + \gamma_4 \log(x_4) + u \tag{5}$$

- 2. Test competing specifications
  - (a) (F) test for specification (4):  $H_0: \gamma_1 = \gamma_2 = 0$ .
  - (b) (F) test for specification (3):  $H_0: \gamma_3 = \gamma_4 = 0$ .

#### 9.1.3 Non-nested alternatives: Davidson-MacKinnon test

Let  $\hat{y}_3$  and  $\hat{y}_4$  denote the fitted values from (3) and (4) respectively. If model (3) holds with  $\mathbb{E}[u|x_1,x_2]=0$ , the fitted values from the other model, (4), should be insignificant when added to equation (3).

#### **Procedures**

1. Test for specification (3) with  $H_0: \theta_1 = 0, H_1: \theta_1 \neq 0$ .

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \theta_1 \hat{y}_4 + u \tag{6}$$

2. Test for specification (4) with  $H_0: \theta_1 = 0, H_1: \theta_1 \neq 0$ .

A significant t statistic (against a two-sided alternative) is a rejection of (4).

$$y = \beta_0 + \beta_1 \log(x_1) + \beta_2 \log(x_2) + \theta_1 \hat{y}_3 + u \tag{7}$$

#### Remark 9.3 (Porblems).

- 1. In Davison-MacKinnon test, its possible for us to reject or accept both specifications.
  - (a) If neither rejected, use adjusted R-square to choose one model.
  - (b) If both rejected, find another alternative.
- 2. Note that a rejection of (3) does not mean (4) is the correct model.
- 3. The case when competing models have different dependent variables could be problematic.  $(y = \dots$  against  $\log(y) = \dots)$

#### 9.2 Proxy Variables

#### 9.2.1 Procedures

For the original model

$$y = \beta_0 + \beta_1 x_1 + \dots + \beta_k x_k^* + u \tag{8}$$

where  $x_k^*$  is unobserved.

(1)Select proxy Choose an observed variable  $x_k$  is a proxy for  $x_k^{uob}$  such that

$$x_k^* = \delta_0 + \delta_k x_k + v_3 \tag{9}$$

**Assumption 9.1.** Typically we want  $\delta_k > 0$ , and no restriction on  $\delta_0$ .

(2)Plug-in solution to the omitted variables problem directly replace  $x_k^*$  with  $\delta_0 + \delta_k x_k + v_3$ 

$$y = (\beta_0 + \beta_k \delta_0) + \beta_1 x_1 + \dots + \frac{\beta_k \delta_k x_k}{\delta_k x_k} + (u + \beta_k v)$$
(10)

Assumption 9.2. For a consistent estimator, we need to assume that

- 1. u is uncorrelated with  $x_1, x_2, \ldots, x_k^*, x_k$ .
- 2. v is uncorrelated with  $x_1, x_2, \ldots, x_k$ .

$$\mathbb{E}[x_k^*|x_1, x_2, \dots, x_k] = \mathbb{E}[\delta_0 + \delta_k x_k + v|x_1, x_2, \dots, x_k] = \delta_0 + \delta_k x_k$$

**Remark 9.4.** Under above assumptions and regressing y on  $x_1, x_2, \ldots, x_k$ , the OLS estimator for  $(\beta_1, \beta_2, \ldots, \beta_{k-1})$  is still **consistent** and **unbiased**. But for intercept and  $k^{th}$  coefficient, we are effectively estimating  $\beta_0 + \delta_0 \beta_k$  and  $\delta_k \beta_k$ .

#### 9.2.2 Proxy Bias

If  $x_k^*$  is correlated with all  $\{x_1, x_2, \dots, x_k\}$  (collinearity), i.e.

$$x_k^* = \delta_0 + \delta_1 x_1 + \delta_2 x_2 + \dots + \delta_k x_k + v_k$$

the for the coefficient of  $x_j$  in the original regression,

$$plim(\hat{\beta}_i) = \beta_i + \beta_k \delta_i$$

which means the estimation is still biased. In this case, using a proxy variable will not solve the omitted variable bias problem.

#### 9.3 Measurement Error in an Explanatory Variable

Consider the model

$$y = \beta_0 + \beta_1 x_1^* + u$$

but we can only observe  $x_1 = x_1^* + e_1$ .

Assumption 9.3. Assuming measurement error satisfies

$$\mathbb{E}[e_1] = 0$$

and the regression model becomes if we regress y on the observed  $x_1$ .

$$y = \beta_0 + \beta_1 x_1 + (u - \beta_1 e_1) \tag{11}$$

**Assumption 9.4.** u is uncorrelated with both  $x_1$  and  $x_1^*$ , i.e.  $x_1$  does not affect y after  $x_1^*$  has been controlled for.

**9.3.1** Case 1:  $Cov(x_1, e_1) = 0$ 

**Remark 9.5.** Since  $e_1 = x_1 + x_1^*$ , if  $Cov(x_1, e_1) = 0$  then  $Cov(x_1^*, e_1) \neq 0$ .

Remark 9.6.

$$\mathbb{E}[u - \beta_1 e_1] = \mathbb{E}[u] - \beta_1 \mathbb{E}[e_1] = 0$$

MLR.3 still holds and estimator  $\hat{\beta}_1$  is still consistent.

Remark 9.7. Note that

$$Var(u - \beta_1 e_1) = \sigma_u^2 + \beta_1^2 \sigma_{e_1}^2$$

the variance of estimators is inflated unless  $\beta_1 = 0$ .

9.3.2 Case 2  $Cov(x_1^*, e_1) = 0$ : Classical errors-in-variance(CEV) Remark 9.8.

$$Cov(x_1, e_1) = \mathbb{E}[(x_1 - \overline{x}_1)(e_1 - \overline{e}_1)]$$

$$= \mathbb{E}[x_1 e_1]$$

$$= \mathbb{E}[(x_1^* + e_1)e_1]$$

$$= \mathbb{E}[x_1^* e_1 + e_1^2]$$

$$= 0 + \mathbb{E}[e_1^2]$$

$$= \mathbb{E}[(e_1 - \overline{e}_1)^2]$$

$$= \sigma_{e_1}^2 \neq 0$$

Thus the covariance between  $x_1$  and  $x_1$  is equal to the variance of the measurement error under CEV assumption.

**Remark 9.9.** From equation (11), the new residual is  $(u - \beta_1 e_1)$  and

$$Cov(x_1, u - \beta_1 e_1) = \sum (x_1 - \overline{x}_1)(u - \beta_1 e_1)$$

$$= \sum x_1 u - \beta_1 \sum x_1 e_1$$

$$= Cov(x_1, u) - \beta_1 \sum (x_1 - \overline{x}_1)(e_1 - 0)$$

$$= 0 - \beta_1 Cov(x_1, e_1)$$

$$= \sigma_{e_1}^2 \neq 0$$

this fails MLR.4 and the OLS regression of y on  $x_1$  gives a biased and inconsistent estimator.

## 9.4 Measurement Error in Dependent Variable

Consider model

$$y^* = \mathbf{X}\vec{\beta} + u \tag{12}$$

and the actually observed y is  $y = y^* + e_0$ , with **measurement error**  $e_0$ . If we regress the observed y on explanatory variables, we are effectively estimating

$$y = \mathbf{X}\vec{\beta} + (u + e_0) \tag{13}$$

Remark 9.10. Assuming the measurement error in y is statistically independent of each explanatory variable, the OLS estimator from (12) is consistent and unbiased (Gauss-Markov Holds).

**Remark 9.11.** Note that we would now have higher residual variance  $\sigma_u^2 + \sigma_{e_0}^2$  and the variance for OLS estimator is inflated

$$Var(\vec{\beta}) = (\sigma_u^2 + \sigma_{e_0}^2)(\mathbf{X}'\mathbf{X})^{-1}$$

## 10 Slide 13: Instrumental Variables

## 10.1 Endogeneity

**Definition 10.1.** If a predictor  $x_j$  is correlated with u for any reason, and MLR.4 is violated, then  $x_j$  is said to be an **endogenous** explanatory variable.

$$\mathbb{E}[u|\mathbf{x}] \neq 0$$

$$y = \beta_0 + \beta_1 x_1 + \dots + \beta_k x_k + u \tag{1}$$

#### Sources of Endogeneity

- Omitted variable bias.
- Sample selection bias.
- Simultaneity (bidirectional causality).
- Measurement error bias.

#### Remedies

- Control for confounding variables. 1
- Instrumental variables or two stage least square.
- Differences in difference. (repeated cross-section data)
- Fixed effects. (panel data)

<sup>&</sup>lt;sup>1</sup>A **confounding variable** is a variable that influences both the dependent variable and independent variable causing a spurious association.

## 10.2 Instrumental Variables

The Problem For the simple regression model

$$y = \beta_0 + \beta x + u$$

estimator  $\hat{\beta}$  would be biased if endogeneity presents  $(Cov(x, u) \neq 0)$ . Then OLS is actually estimating

$$\frac{\partial y}{\partial x} = \beta + \frac{\partial u}{\partial x}$$

instead of purely  $\beta$ , where  $\frac{\partial u}{\partial x} \neq 0$  due to endogeneity.

We need a method to generate only exogenous variation in x, without changing u, and measure its impact on y via  $\beta$  only.

**Definition 10.2.** An **instrument** z for predictor x is a variable the property that

1. (Exogeneity condition) uncorrelated with u.

$$Cov(z, u) = 0$$

2. (Relevance condition) correlated (either positively or negatively) with x.

$$Cov(z, x) \neq 0$$

Remark 10.1. There no perfect test for exogeneity condition and we have to argue it by appealing to economic theory. So we cannot prove exogeneity condition formally.

**Remark 10.2.** For the relevance condition, we can test it by testing the significance of  $\pi_1$  in the regression below

$$x = \pi_0 + \pi_1 z + v$$

## 10.3 Implementation of IV: Method of Moments

#### **Procedure**

- 1. Identify  $\beta$  in terms of population moments.
- 2. Replace the population moments with the sample moments.<sup>2</sup>

<sup>&</sup>lt;sup>2</sup>By **analogy principle**, such replacement will lead to a consistent estimator.

#### 10.3.1 In Simple Regression

**Identification** Consider the model with instrumental variable z for x,

$$y = \beta_0 + \beta_1 x + u$$

subtract both sides the corresponding expectations,

$$y - \mathbb{E}[y] = \beta_1(x - \mathbb{E}[x]) + (u - \mathbb{E}[u])$$

multiplying both sides by  $(z - \mathbb{E}[z])$  and take expectation

$$\mathbb{E}[(y - \mathbb{E}[y])(z - \mathbb{E}[z])] = \beta_1 \mathbb{E}[(x - \mathbb{E}[x])(z - \mathbb{E}[z])] + \mathbb{E}[(u - \mathbb{E}[u])(z - \mathbb{E}[z])]$$

$$\implies Cov(y, z) = \beta_1 Cov(x, z) + Cov(u, z)$$

By exogeneity condition and relevance condition

$$Cov(x, z) \neq 0 \land Cov(z, u) = 0$$

$$\implies \beta_1 = \frac{Cov(y,z)}{Cov(x,z)}$$

**Replacement** calculate the <u>sample</u> covariances between y, z and x, z and substitute into above expression, the  $\overline{IV}$  estimator of  $\beta_1$  is

$$\hat{\beta}_1 = \frac{\sum_i (y_i - \overline{y})(z_i - \overline{z})}{\sum_i (x_i - \overline{x})(z_i - \overline{z})}$$

and the **IV estimator** of  $\beta_0$  is

$$\hat{\beta}_0 = \overline{y} - \hat{\beta}_1 \overline{x}$$

**Remark 10.3.** When z=x the IV estimator is equivalent to the OLS estimator. And the IV estimator is consistent even when MLR.4 does not hold.

#### 10.3.2 Inference

Assuming

$$\mathbb{E}[u^2|z] = \sigma^2 = Var(u)$$

Then the variance of  $\hat{\beta}_1$  is

$$Var(\hat{\beta}_1) = \frac{\sigma^2}{n\sigma_x^2 \rho_{xz}^2}$$

with sample analogs and  $R_{x,z}^2$  from regression of  $x_i$  on  $z_i$ , the estimated variance is

$$\widehat{Var(\hat{\beta}_1)} = \frac{\hat{\sigma}^2}{SST_x R_{x,z}^2}$$

Note that the variance of OLS estimator is estimated to be

$$\widehat{Var(\hat{\beta}_1)} = \frac{\hat{\sigma}^2}{SST_r}$$

Therefore the IV estimator is always larger than OLS variance.

Note that as  $z \to x$ ,  $R_{x,z}^2 \to 1$  and IV estimator is approaching and ultimately equivalent to the OLS estimator.

#### 10.3.3 Properties

If z and x are weakly correlated (aka. weak instrument).

- IV estimators can have large standard errors. (small  $R_{x,z}^2$ )
- IV estimators can have large <u>asymptotic bias</u> if  $Corr(z, u) \neq 0$  (since we cannot check exogeneity condition formally, so we cannot rule out this probability).

For IV estimator,

$$plim\hat{\beta}_{1,IV} = \beta_1 + \frac{Corr(z,u)\sigma_u}{Corr(z,x)\sigma_x}$$

compared with OLS estimator

$$plim\hat{\beta}_{1,OLS} = \beta_1 + Corr(x, u) \frac{\sigma_u}{\sigma_x}$$

**Remark 10.4.** The  $R^2$  in IV estimation can be negative, and we should be careful about interpreting  $R^2$  in IV estimation.

## 10.4 IV in Multiple Regression

Consider the multiple regression model on k predictors, where  $y_2$  is endogenous. The **structural model** is given in (2) below.

$$y_1 = \beta_0 + \beta_1 y_2 + \beta_2 z_1 + \dots + \beta_k z_{k-1} + u_1 \tag{2}$$

**Identification** Let  $z_k$  be an instrumental variable for  $y_2$  the exogenity condition can be expressed as

$$Cov(z_k, u_1) = 0$$

and assuming all other explanatory variables  $z_i$  are uncorrelated with  $u_1$ . Also assume the zero-mean-error,

$$Cov(z_i, u_1) = 0, \ \forall i \in \{1, 2, \dots, k - 1\}$$
  
 $\mathbb{E}[u_1] = 0$ 

Above conditions can be re-written as

$$\mathbb{E}[z_i u_1] = 0, \ \forall i \in \{1, 2, \dots, k\}$$
  
 $\mathbb{E}[u_1] = 0$ 

Above k + 1 equations identify  $\beta_0, \beta_1, \ldots, \beta_k$ .

**Replacement** Replacing  $u_1$  with  $\hat{u}_1$  from regression (2),

$$\sum_{i=1}^{n} (y_{i1} - \hat{\beta}_0 - \hat{\beta}_1 y_{i2} - \hat{\beta}_2 z_{i1} - \dots - \hat{\beta}_k z_{k-1}) = 0$$

$$\sum_{i=1}^{n} z_{i1} (y_{i1} - \hat{\beta}_0 - \hat{\beta}_1 y_{i2} - \hat{\beta}_2 z_{i1} - \dots - \hat{\beta}_k z_{k-1}) = 0$$

$$\sum_{i=1}^{n} z_{i2} (y_{i1} - \hat{\beta}_0 - \hat{\beta}_1 y_{i2} - \hat{\beta}_2 z_{i1} - \dots - \hat{\beta}_k z_{k-1}) = 0$$

$$\vdots$$

$$\sum_{i=1}^{n} z_{ik-1} (y_{i1} - \hat{\beta}_0 - \hat{\beta}_1 y_{i2} - \hat{\beta}_2 z_{i1} - \dots - \hat{\beta}_k z_{k-1}) = 0$$

And solving above k+1 equations and replacing give the IV estimations of  $\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k$ .

The relevance condition  $Corr(y_2, z_k)$  can be verified using **reduced-form(auxiliary)** equation below with  $H_0: \pi_k = 0$  and  $H_1: \pi_k \neq 0$ .

$$y_2 = \pi_0 + \pi_1 z_1 + \pi_2 z_2 + \dots + \pi_k z_k + v_2$$

## 11 Slide 14: Two Stage Least Square

## 11.1 Procedure

Motivation Multiple good instrumental variables for the endogenous variable

**Structural Equation:** 

$$y = \beta_0 + \beta_1 y_2 + \beta_2 z_1 + u_1 \tag{1}$$

with Reduced Form Equation:

$$y_2 = \pi_0 + \pi_1 z_1 + \pi_2 z_2 + \pi_3 z_3 + v_2 \tag{2}$$

where at least one of  $\pi_2, \pi_2 \neq 0$ . (Relevance condition)

#### 2SLS Procedures

1. **Stage 1** Run regression on REF and compute  $\hat{y}_2$ , which is a linear combination of  $z_1, z_2, z_3$ . So  $\hat{y}_2 \perp u_1$  by exogeneity condition. Note that,  $v_2 \not \perp u_1$ .

$$\hat{y}_2 = \hat{\pi}_0 + \hat{\pi}_1 z_1 + \hat{\pi}_2 z_2 + \hat{\pi}_3 z_3$$

2. Check significance of  $z_2$  and  $z_3$  to verify relevance condition.

3. **Stage 2** Regress  $y_1$  on  $\hat{y}_2$  and  $z_1$  to obtain  $\hat{\beta}_{1,2SLS}$ .

**Remark 11.1.** The first stage of 2SLS removes endogeneity of  $y_2$  (dropped with  $v_2$ ).

#### 2SLS Procedures: general case

- 1. **Stage 1** For each included endogenous explanatory variables, construct its reduced form equation with instrumental variables (excluded exogenous) and included exogenous variables.
- 2. Check significance of every instrumental variables using t test and/or the joint significance of all instrumental variables used.
- 3. Stage 2 Regress y all included exogenous variables and the estimated reduced form equations  $(\hat{y}_j)$  for all included endogenous variables.

**Remark 11.2** (Number of IVs, the general case). With k predictors in total, if m of them are endogenous, we need at least m excluded exogenous variables to run 2SLS.

Otherwise, in the second stage regression, we would have less explanatory variables than parameters to be estimated. (perfect collinearity)

## 11.2 Equivalence between IV and 2SLS

On the simple regression

$$y = \beta_0 + \beta_1 x + u$$

and let z be the excluded exogenous variable used as the instrumental for x. For simplicity, assume  $\overline{x} = \overline{y} = \overline{z} = 0$ .

Then IV estimator

$$\hat{\beta}_{1,IV} = \frac{Cov(z,y)}{Cov(z,x)} = \frac{\sum yz}{\sum xz}$$

And 2SLS estimator

$$\begin{split} \hat{\beta}_{1,2SLS} &= \frac{\sum (\hat{x} - \overline{\hat{x}})(y - \overline{y})}{\sum (\hat{x} - \overline{\hat{x}})^2} \\ &= \frac{\sum \hat{x}y}{\sum \hat{x}^2} = \frac{\sum (\hat{\pi}_0 + \hat{\pi}_1 z)y}{\sum (\hat{\pi}_0 + \hat{\pi}_1 z)^2} \\ &= \frac{\sum \hat{\pi}_1 yz}{\sum \hat{\pi}_1^2 z^2} = \frac{1}{\hat{\pi}_1} \frac{\sum yz}{\sum z^2} \\ &= \frac{\sum z^2}{\sum zx} \frac{\sum yz}{\sum z^2} = \frac{\sum yz}{\sum xz} = \hat{\beta}_{1,IV} \end{split}$$

## 11.3 Evaluating 2SLS

### 11.3.1 Regressor Endogeneity

OLS is BLUE, if OLS is consistent we should not use the relatively less efficient 2SLS.

		$H_0$	$H_1$
	$\hat{ec{eta}}_{OLS}$	Consistent and Efficient	Inconsistent
	$\hat{ec{eta}}_{2SLS}$	Consistent but less Efficient	Consistent

Hausman's Test for OLS Consistency If  $H_0$  if failed to be rejected use OLS as BLUE, if we reject  $H_0$  then use 2SLS.

$$H_0: plim \ \hat{\beta}_{OLS} = plim \ \hat{\beta}_{2SLS} = \vec{\beta}$$
  
$$H_1: plim \ \hat{\beta}_{OLS} \neq \vec{\beta} \land plim \ \hat{\beta}_{2SLS} = \vec{\beta}$$

Take

$$d = \hat{\beta}_{OLS} - \hat{\beta}_{2SLS}$$

Under the Null Hypothesis, a normalized d statistic is distributed as a  $\chi_g$  where g is the number of parameters in the test.

#### 11.3.2 Instrument Relevance

Check the significance of instrumental variables in **reduced form equations** with t-test or F-test. If certain IV is not significant in reduced form equation, then do not use this IV.

Consider model

$$y_1 = \beta_0 + \beta_1 y_2 + \beta_2 z_1 + \beta_3 z_2 + u \tag{3}$$

where  $y_2$  is suspended to be endogenous and  $(z_3, z_4)$  are used as instrumental variables.

### 11.3.3 Instrument Exogeneity

Theoretically impossible to test.

- Solution (1): economic sense.
- Solution (2): over-confidence test (with  $z_3$  and  $z_4$  as instrumental variables)
  - 1. Assume  $z_3$  is a valid instrumental variable, use  $z_3$  as IV to recover  $\hat{u}_1$ .

$$\hat{u}_1 = y_1 - \hat{\beta}_{0,IV} - \hat{\beta}_{1,IV}y_2 - \hat{\beta}_{2,IV}z_1 - \hat{\beta}_{3,IV}z_3$$

2. Test if  $Cov(z_4, \hat{u}_1) = 0$  to test the validity of  $z_4$ .

$$\hat{u}_1 = \delta_0 + \delta_1 z_1 + \delta_2 z_2 + \delta_3 z_3 + \delta_4 z_4 + \epsilon$$

with  $H_0$  all insignificant (exogenous) and  $H_1$  at least one of  $z_i$  is significant (endogenous). And under  $H_0$ ,

$$nR_{u,z}^2 \sim \chi_q^2$$

where q is the **degree of overconfidence**, which is the number of IV excluded from the main regression minus the number of endogenous variables.

3. Use  $z_4$  to recover  $\hat{u}_1$  and test again.

#### 12 Slide 15: Simultaneous Equations

Motivation Variables are jointly determined.

**Example 12.1.** Linear supply and demand framework.

$$\begin{cases}
p = \beta_{11} + \beta_{12}q_s + \beta_{13}z_1 + u_1 \\
p = \beta_{21} + \beta_{22}q_d + \beta_{23}z_1 + u_2 \\
p_d = p_s
\end{cases}$$

where  $z_1$  and  $z_2$  are exogenous variables. (aka supply and demand shifters)  $q_s, q_d, p$  are endogenous variables.  $u_1$  and  $u_2$  are structural errors.

#### 12.1 Simultaneity Bias in OLS

Above simultaneous model can be written as reduced from below

$$\begin{cases} q_{s} = q_{d} = \frac{1}{\beta_{12} - \beta_{22}} (\beta_{11} - \beta_{21} + \beta_{13}z_{1} - \beta_{23}z_{2} + u_{1} - u_{2}) \\ p = \frac{\beta_{12}}{\beta_{12} - \beta_{22}} (\beta_{11} - \beta_{21} + \beta_{13}z_{1} - \beta_{23}z_{2} + u_{1} - u_{2}) + \beta_{11} + \beta_{13}z_{1} + u_{1} \end{cases}$$

$$\implies \begin{cases} q_{s} = q_{d} = \pi_{11} + \pi_{12}z_{1} + \pi_{13}z_{2} + v_{1} \\ p = \pi_{21} + \pi_{22}z_{1} + \pi_{23}z_{2} + v_{2} \end{cases}$$

$$(2)$$

$$\Rightarrow \begin{cases} q_s = q_d = \pi_{11} + \pi_{12}z_1 + \pi_{13}z_2 + v_1 \\ p = \pi_{21} + \pi_{22}z_1 + \pi_{23}z_2 + v_2 \end{cases}$$
 (2)

From (1), obviously q and p are correlated with  $u_1, u_2$ . And  $v_1, v_2 \not\perp u_1, u_2$ .

Notation 12.1.  $\beta$ : structural form parameters.  $\pi$ : reduced form parameters.  $(v_1, v_2)$ : reduced form errors.

And note that  $z_1, z_2 \perp v_1, v_2$ .

If we use (2) and OLS to regress q and p based on exogenous variables  $z_1, z_2$ , we will get consistent reduced form parameters but not structural form parameters.

#### 12.2IV Estimator and 2SLS

**Key** From (1) or (2), we can show that p, q are correlated with  $z_1, z_2$ . (Relevance condition)

Also  $z_1, z_2 \perp v_1, v_2$  implies exogeneity condition holds.

Use  $z_1$  and  $z_2$  as instrument for p, q.

#### **Procedures**

- 1. (Stage 1 OLS) Regress q on  $z_1, z_2$ .
- 2. Estimate  $\hat{q} = \hat{\pi}_{11} + \hat{\pi}_{12}z_1 + \hat{\pi}_{13}z_2$ .
- 3. (Stage 2 OLS)
  - (a) Regress p on  $\hat{q}, z_1$  to obtain supply function.
  - (b) Regress p on  $\hat{q}, z_2$  to obtain demand function.

Special case consider the case

$$\begin{cases}
q_s = \alpha_1 p + \beta_1 z_1 + u_1 \\
q_d = \alpha_2 p + u_2 \\
q_s = q_d
\end{cases}$$
(3)

We cannot recover  $q_s$  since  $\hat{p}$  would be a function of  $z_1$  only and we would encounter perfect co-linearity when regress  $q_s$  on  $\hat{p}, z_1$ .

In general, variables that appear **only** in the demand function can be valid instrument to estimate supply, vice versa. (Otherwise, perfect multi-collinearity)

**Exclusion Restriction**  $z_1$  omitted in demand and  $z_2$  omitted in supply.

Rank Condition (Sufficiency, not covered) tells us when such exclusion restrictions are sufficient to estimate structural parameters and ensures unique solution for structural parameters.

**Order Condition** (Necessary condition for identification) At least as many excluded exogenous variables (instrument) are required as included endogenous variables in the structural equation. (Otherwise, perfect multi-collinearity)

Remark 12.1. In 2SLS, we are basically replacing *included endogenous variables* with linear combinations (OLS prediction) of *all exogenous variables*. If one equation is unidentified, the total number of exogenous variables <u>after</u> replacement would be less than number of parameters

**Definition 12.1.** (Identifications)

Over identified equation: more excluded exogenous variables than included endogenous variables.

**Just identified** same number of excluded exogenous variables and included endogenous variables.

Unidentified less excluded exogenous variables than included endogenous variables.

Remark 12.2. Only over-identified and just identified equations can be correlated estimated by 2SLS.

## 13 Slide 17: Intro to Time Series

**Definition 13.1.** A **time series**(or stochastic process) is a sequence of random variables

$$\{y_t\}, \quad t = 1, 2, \dots, n$$

- Order matters.
- Only a single *realization* of "economic history" (a stochastic process).
- Model the statistics as if we could observe repeated realization of the entire sequence.

**Example 13.1** (Static Phillips Curve). captures contemporaneous relationships.

$$inflation_t = \beta_0 + \beta_1 unemployment_t + u_t$$

Example 13.2 (Expectation Augmented Phillips Curve).

$$\Delta infl_t = infl_t - infl_{t-1} = \beta_0 + \beta_1 unemp_t + u_t$$

## 13.1 Random Walk

Definition 13.2. Random walk process.

$$y_t = y_{t-1} + e_t$$

where  $e_t$  follows white noise satisfying

- 1.  $\mathbb{E}[e_t] = 0$
- 2.  $Var(e_t) = \sigma_e^2$
- 3.  $\mathbb{E}[e_t e_s] = 0$ ,  $t \neq s$  (i.e.  $Cov(e_t, e_s) = 0$ ,  $t \neq s$ )

#### **Properties of Random Walker Process**

- 1.  $y_t = \sum_{i=1}^t e_i + y_0$
- 2.  $Var(y_t) = Var(y_0) + t^2 \sigma_e^2$
- 3.  $\mathbb{E}[y_t y_{t+h}] = \mathbb{E}[y_t (y_t + e_{t+1} + \dots + e_{t+h})] = \mathbb{E}[y_t^2]$

(a) If 
$$\mathbb{E}[y_0] = Var(y_0)$$
 (i.e.  $y_0 = 0$ ), then  $\mathbb{E}[y_t^2] = t^2 \sigma_e^2$ .

#### **13.2** Trend

- If trend presents (i.e. t should be included as a regressor), then ignoring the trend would introduce omitted variable bias.
- (In practice) partialling out trends.
- Note:  $R^2$  tends to be high when using trending data and the high  $R^2$  may reflect the explanatory power of trend (t) but not the explanatory power of  $\mathbf{x}_t$

## 13.3 Seasonality

**Simple Solution**: including dummy variables representing different sections in a complete season loop.

$$y_t = \alpha_0 + \alpha_1 t + \delta_1 Q_{t1} + \delta_2 Q_{t2} + \delta_3 Q_{t3} + \beta \mathbf{x} + u_t$$

where  $\alpha_1 t$  captures the trend and  $\delta_i Qti$  captures the seasonalities.

#### 13.4 Serial Correlation

Definition 13.3.

$$\mathbb{E}[u_t u_s | \mathbf{X}] \neq 0$$
, for  $t \neq s$ 

**Remark 13.1.** Similar to heteroskedasticity,  $\mathbb{E}[u_t^2|\mathbf{X}] = \sigma_t^2 \neq \sigma^2$ .

Consequences OLS will still be

- 1. Consistent
- 2. and unbiased

but

- 1. not the best (i.e. not the most efficient)
- 2. biased/inconsistent variance-covariance matrix and biased inferences.

## 13.5 Stationarity

**Definition 13.4.** A stochastic process

$$\{x_t|t=1,2,\dots\}$$

is **stationary** if the *joint distribution* of  $\{x_{t1}, x_{t2}, \dots\}$  is the same as  $\{x_{t1+h}, x_{t2+h}, \dots\}$ .

- 1.  $x_t$  is identically distributed for all  $t \in \mathbb{N}$ ,
- 2. and  $corr(x_t, x_{t+1}) = corr(x_{t+h}, x_{t+h+1})$ .

### 13.6 Weakly Dependent Time Series

**Definition 13.5.** A time series is **weakly dependent** if, loosely speaking,  $x_t$  and  $x_{t+h}$  are "almost independent" as n increases without bound. Similar to the *random sample* assumption in MLR.

$$\lim_{h \to \infty} corr(x_t, x_{t+h}) = 0$$

Remark 13.2. To use OLS on time series, the series must be both

- 1. Stationary
- 2. and weakly dependent
